

**CLASS 1**  
**BLC-150: THE ALGEBRA WORKSHOP**

A prime number is a natural number (counting number or positive integer) **greater than 1 that cannot be formed by multiplying two smaller natural numbers.** Put another way, a prime number is a natural number that has exactly two distinct natural number factors (or divisors), namely 1 and the number itself.

A natural number greater than 1 that is not prime is called a composite number.

Is 2 a prime number? It's "greater than 1." Yes. But can it be made "by multiplying two smaller natural numbers"?

No. There are no natural numbers smaller than 2 which can be multiplied together to make 2. The only possibility of a natural number less than 2 is 1, and there is no way to multiply 1 by 1 to get 2. Therefore, 2 is prime.

Put another way, the only natural number factors of 2 are 1 and 2, ... 1 and itself. Therefore 2 is prime.

How to find prime numbers?

One way is the Sieve of Eratosthenes (d. 194 BC)

- a. Start with 2, the first prime. Cross out every number that is a multiple of 2 on this list. That will be every even number greater than 2. For example, you will cross out 26. Why? Because it is even, and because it is a composite number. It can be expressed as  $2 \times 13$ . Therefore 26 is not a prime number. A prime number cannot be expressed as a product of two lesser natural numbers.
- b. Go to the next number that is not crossed out. That would be 3. Is it a prime number? Can it be expressed as a product of two natural numbers less than 3? The only natural number candidates are 1 and 2. Can you multiply  $1 \times 1$ ,  $1 \times 2$ , or  $2 \times 2$  and get 3? No. Therefore 3 is prime. Its only natural number factors are 1 and 3. Now cross out every 3rd number after 3. E.g. Cross out 6, 9, 12, 15, etc.
- c. Find the next number that is not crossed out. That should be a 5. [4 should be crossed out from step a.] Is 5 prime? Are there any factors of 5 that are natural numbers less than 5? If so, cross out every fifth number after 5. E.g. 10, 15, 20, etc.
- d. Go to then next number that is not crossed out and repeat step c. Do this until you can't anymore.

What remains are the primes up to 100.

|              |    |    |    |    |    |    |    |    |     |
|--------------|----|----|----|----|----|----|----|----|-----|
| <del>1</del> | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10  |
| 11           | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20  |
| 21           | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30  |
| 31           | 32 | 33 | 34 | 35 | 36 | 37 | 38 | 39 | 40  |
| 41           | 42 | 43 | 44 | 45 | 46 | 47 | 48 | 49 | 50  |
| 51           | 52 | 53 | 54 | 55 | 56 | 57 | 58 | 59 | 60  |
| 61           | 62 | 63 | 64 | 65 | 66 | 67 | 68 | 69 | 70  |
| 71           | 72 | 73 | 74 | 75 | 76 | 77 | 78 | 79 | 80  |
| 81           | 82 | 83 | 84 | 85 | 86 | 87 | 88 | 89 | 90  |
| 91           | 92 | 93 | 94 | 95 | 96 | 97 | 98 | 99 | 100 |

Now, choose a number that is crossed off from the table above.  
How about 77.

What are its prime factors? What numbers lower than 77 can be multiplied together to get 77?  
Answer: 11 and 7. These are the prime factors of 77.

How about 42? What are its prime factors?  
Well.... 2 and 21 multiplied together give 42. 2 and 21 are factors, but are they the prime factors?  
One of them is. 2, but 21 is not prime, so you need to keep going...  
 $42 = 2 \times 21 = 2 \times 3 \times 7$ . This is the **prime factorization** of 42.

Larger numbers can get trickier.

The standard method for prime factorization is graphical, so I'll just present this the picture.

|  |   |  |  |
|--|---|--|--|
|  | <p>The prime factorization of 360 is</p> $2 \cdot 2 \cdot 2 \cdot 5 \cdot 3 \cdot 3$ <p>or in order...</p> $2 \cdot 2 \cdot 2 \cdot 3 \cdot 3 \cdot 5$ <p>or fancy-style...</p> $2^3 \cdot 3^2 \cdot 5$ | <p>There is more than one way to skin a cat...</p> <p>But you end up with the same prime factorization.</p> $2 \cdot 3 \cdot 2 \cdot 3 \cdot 3 \cdot 5$ <p>or fancy-style...</p> $2^3 \cdot 3^2 \cdot 5$ |  |
